Quantum Field Theory

Xinyu Xiang

Jun. 2025

Warning: Lots of possible typos!!!!!!!!!!! **Notations**:

- X: a smooth manifold, usually a compact manifold.
- $\mathcal{E}$: the space of fields, usually infinite dimensional.
- $\mathrm{Conn}(P, X)$: the space of connections on a principal bundle P over X.
- $\mathrm{Maps}(\Sigma, X)$: the space of maps from a surface Σ to X.
- $\Omega^\bullet(X)$: the space of differential forms on X.
- $\Omega_c^\bullet(X)$: the space of differential forms with compact support on X.
- $\mathrm{Vect}(M)$: the space of smooth vector fields on a manifold M, which is Lie algebra of $\mathrm{Diff}(M)$.

1 Day I: Overall Discussion and Mathematical Preliminaries

1.1 Actions and Path Integrals

Action $S : \mathcal{E} \to \mathbf{k}$ where $\mathcal{E}$ always has infinite dimension, and is a field (usually $\mathbb{R}$ or $\mathbb{C}$).

$$\text{QM in Imaginary Time} \xrightarrow{\text{Brownian Motion}} \text{Wiener Measure on Phase Space}$$

$$\text{Asymptotic Analysis} \longrightarrow \text{Perturbative Renormalisation Theory}$$

Example 1.1. *Some Examples of Classical Field Theories*

(a) Scalar Field Theory $\mathcal{E} = C^\infty(X)$

(b) Gauge Theory $\mathcal{E} = \mathrm{Conn}(P, X)$

(c) σ *Model* $\mathcal{E} = Maps(\Sigma, X)$

(d) Gravity $\mathcal{E} = Metrics(X)$ *(More better descriptions does not depends on the background)*

1.2 Observables

Observables are functions on the space of fields, i.e. $\mathcal{O} \in C^\infty(\mathcal{E})$.

Example 1.2 (field theory)**.** *(a) Consider* $X = pt$*, thus* $\mathcal{E} = \mathbb{R}^n$ *for example.*

(b) $\dim X > 0$*, the new algebraic structure arise form topological structures of* X*.*

The Key Point is: Capture the data of open sets of $X \longrightarrow$ Consider the observables supported on open set U of X denoted by $\mathrm{Obs}(U)$ where U is an open set of X.

Local data captures the open sets of X. The relations between open sets captures the global data of $X \longrightarrow$ The algebraic structure of the observables is a sheaf of X.

$$\bigsqcup_i U_i \longrightarrow \bigotimes_i \mathrm{Obs}(U_i)$$

Which implies OPE in physics and factorization algebra in mathematics.

Higher product in QFT: The generalization of products of algebra ('products in any direction instead of left and right') e.g. QM gives only left and right module of an algebra; OPE has products in various directions.

Consider the $\dim X = 2$ case in detailed

Example 1.3 (Holomorphic/Chiral Field Theory). *Various angle of product $A(w)B(z)$ could be denoted by the time of $A(w)$ rotations around $B(z)$, which could be captured by the Fourier mode of $A(w)$, thus one can have*

$$A(w)B(z) = \sum_{m\in\mathbb{Z}} \frac{(A_{(m)B(z)})}{(z-w)^{m+1}}$$

which is the Chiral algebra due to Beilinson and Drinfeld and associated with the Doubult cohomology $H^1_{\bar\partial}(\Sigma^2 - \Delta)$, where Σ^2 is the complex surface and Δ is the diagonal of Σ^2. The higher structure could be captured by the higher cohomology $H^p_{\bar\partial}(\Sigma^2 - \Delta)$, which is the higher chiral algebra associated to the derived holomorphic section.

1.3 de Rham Cohomology

Chain of differential forms $\Omega^\bullet(X)$

$$\Omega^\bullet(X) = \left(\cdots \xrightarrow{\mathrm{d}} \Omega^{n-1}(X) \xrightarrow{\mathrm{d}} \Omega^n(X) \xrightarrow{\mathrm{d}} \Omega^{n+1}(X) \xrightarrow{\mathrm{d}} \cdots\right) \tag{1.1}$$

where d is the exterior derivative, and $\Omega^n(X)$ is the space of n-forms on X. The general construction of differential forms could be constructed over open set U by

$$\Omega^n(U) = \bigoplus_{1\le i_1\le\cdots\le i_n\le n} C^\infty(U)\mathrm{d}x^{i_1}\wedge\cdots\wedge\mathrm{d}x^{i_n}$$

where one can prove that $\mathrm{d}^2 = 0$ and thus $(\Omega^\bullet(U), \mathrm{d})$ is a cochain complex. The cohomology of it is called the de Rham cohomology $H^\bullet(X)$.

Proposition 1.1. *The definition of de Rham cohomology does not depend on the choice of the open set U and the choice of the coordinate system i.e. it is intrinsic $\longrightarrow$ we can define the de Rham cochain complex on smooth manifold X.*

Proof. Consider □

Definition 1.1 (de Rham Cohomology on Compact Support). *Let X be a smooth manifold, then the de Rham cohomology on compact support is defined as*

$$H^\bullet_c(X) = H^\bullet(\Omega^\bullet_c(X), \mathrm{d}) \tag{1.2}$$

where $\Omega^\bullet_c(X)$ is the space of differential forms with compact support.

Theorem 1.2 (Stokes' Theorem). *Let X be a smooth manifold with boundary, then for any $\omega \in \Omega^n(X)$, we have*

$$\int_X \mathrm{d}\omega = \int_{\partial X}\omega$$

which connects the local data $\mathrm{d}\Omega^\bullet(X)$ and the global data ∂X.

Theorem 1.3 (Poincaré Lemma)**.**

$$H^p(\mathbb{R}^n) = \begin{cases} \mathbb{R} & p = 0 \\ 0 & p > 0 \end{cases}, \quad H^p_c(\mathbb{R}^n) = \begin{cases} 0 & p < 0 \\ \mathbb{R} & p = n \end{cases}$$

Generator: $H^p(\mathbb{R}^n) \to$ constant function, $H^p_c(\mathbb{R}^n) \to$ a compact support function $\alpha = f(x)\mathrm{vol}_n$, and $\int_{\mathbb{R}^n} \alpha = 1$.

Proof. □

Important: An *Integration* arises from the de Rham cohomology!

Observation. (1) if $\alpha = \mathrm{d}\beta$ where $\beta \in \Omega^{n-1}_c(X)$, then $\int_X \alpha = 0$, thus the generator is α whose integral is non-zero.

(2) **Dual Site**: Integration could be captured by the cohomology

$$\int_{\mathbb{R}^n} \leftrightarrow H^n_c(\mathbb{R}^n) \cong \mathbb{R}$$

Path integral could be interpreted as the integration over $\mathcal{E}$, which leads to consider the cohomology of it.

□

1.4 Cartan Formula

Vector fields could acts on smooth functions via

$$V(f) = V^i \frac{\partial f}{\partial x^i} = \frac{\mathrm{d}}{\mathrm{d}t} f(\varphi_t(x))\bigg|_{t=0} = \frac{\mathrm{d}}{\mathrm{d}t} \varphi_t^* f(x)\bigg|_{t=0}$$

Such an action could be extended to differential forms by

$$\mathrm{Vect}(M) \ni V : \alpha \mapsto \mathcal{L}_V \alpha = \frac{\mathrm{d}}{\mathrm{d}t} \varphi_t^* \alpha\bigg|_{t=0}$$

which has the property $\mathcal{L}_V(\alpha \wedge \beta) = \mathcal{L}_V \alpha \wedge \beta + \alpha \wedge \mathcal{L}_V \beta$, which implies that the Lie derivative is a derivation on the algebra of differential forms with degree 0. And we have contraction ι_V which is a derivation of degree -1 on the algebra of differential forms.

$$\mathcal{L}_V = \mathrm{d}\iota_V + \iota_V \mathrm{d}$$

Lie derivative is homotopy trivial i.e. chain homotopic.

1.4.1 Proof of Poincaré Lemma

Use Cartan Formula, one can proof Poincaré Lemma.

Proof. Rescaling invariance of $\mathbb{R}^n$ leads to the Euler vector field $E = x^i \frac{\partial}{\partial x^i}$. One can consider the associated diffeomorphism φ_t, where we assume $\varphi_0 = 1$ and thus $\varphi^*_{-\infty}\alpha = 0$, thus the closed form α could be rewritten as

$$\begin{aligned} \alpha &= \varphi_0^* \alpha - \varphi^*_{-\infty} \alpha \\ &= \int_{-\infty}^0 \frac{\mathrm{d}}{\mathrm{d}t} \varphi_t^* \alpha \mathrm{d}t \\ &= \int_{-\infty}^0 \mathcal{L}_E(\varphi_t^* \alpha) \mathrm{d}t \end{aligned}$$

using the Cartan formula and $\mathrm{d}\varphi^* = \varphi^*\mathrm{d}$, we have

$$\alpha = \mathrm{d}\int_{-\infty}^{0} \varphi_t^* \iota_E \alpha \,\mathrm{d}t = \mathrm{d}\beta,$$

thus, the closed form α is exact, which implies that the de Rham cohomology $H^p(\mathbb{R}^n)$ is trivial for $p > 0$. The same idea could be applied to the de Rham cohomology on compact support $H_c^p(\mathbb{R}^n)$. $\square$

2 Day II: Classical Mechanics
